ABSTRACT

A biopsy device includes a body, a probe cannula, a cutter, a vacuum source, a tissue sample holder, and a flexible tube. The probe cannula extends distally from the body and defines an internal passage with a side aperture. The cutter is translatable relative to the probe cannula to sever a tissue sample received in the probe cannula. The vacuum source is in communication with the cutter. The tissue sample holder includes a vacuum port on the exterior surface to communicate with the vacuum source and a removable portion to hold solid tissue samples. The removable portion is selectively removable from the tissue sample holder and includes a straining member to separate fluids from solids. The flexible tube couples the tissue sample holder with the body such that the tissue sample holder is flexibly spaced away from the body.

BIOPSY DEVICE WITH INTEGRAL VACUUM ASSIST AND TISSUE SAMPLE AND FLUID CAPTURING CANISTER

CROSS REFERENCE TO RELATED APPLICATIONS

The present application is a continuation of co-pending and commonly-owned U.S. patent application Ser. No. 12/775,780, entitled "BIOPSY DEVICE WITH INTEGRAL VACUUM ASSIST AND TISSUE SAMPLE AND FLUID CAPTURING CANISTER" to Hibner, filed on May 7, 2010, published as U.S. Patent Publication No. 2010/0228146, which is a continuation of U.S. Pat. No. 7,758,515, "BIOPSY DEVICE WITH INTEGRAL VACUUM ASSIST AND TISSUE SAMPLE AND FLUID CAPTURING CANISTER" to Hibner, et al. filed on May 25, 2007, which is a continuation in part of U.S. patent application Ser. No. 10/953,834, "BIOPSY APPARATUS AND METHOD" to Hibner et al., filed 29 Sep. 2004 (U.S. Pat. Publ. No. 2006/0074345), and the disclosures of which are hereby incorporated by reference in their entirety.

FIELD OF THE INVENTION

The present invention relates in general to biopsy devices, and more particularly to biopsy devices having a cutter for severing tissue, and even more particularly to biopsy devices for multiple sampling with a probe remaining inserted

BACKGROUND OF THE INVENTION

When a suspicious tissue mass is discovered in a patient's breast through examination, ultrasound, MRI, X-ray imaging or the like, it is often necessary to perform a biopsy procedure to remove one or more samples of that tissue in order to determine whether the mass contains cancerous cells. A biopsy may be performed using an open or percutaneous method.

An open biopsy is performed by making a large incision in the breast and removing either the entire mass, called an excisional biopsy, or a substantial portion of it, known as an incisional biopsy. An open biopsy is a surgical procedure that is usually done as an outpatient procedure in a hospital or a surgical center, involving both high cost and a high level of trauma to the patient. Open biopsy carries a relatively higher risk of infection and bleeding than does percutaneous biopsy, and the disfigurement that sometimes results from an open biopsy may make it difficult to read future mammograms. Further, the aesthetic considerations of the patient make open biopsy even less appealing due to the risk of disfigurement. Given that a high percentage of biopsies show that the suspicious tissue mass is not cancerous, the downsides of the open biopsy procedure render this method inappropriate in many cases.

Percutaneous biopsy, to the contrary, is much less invasive than open biopsy. Percutaneous biopsy may be performed using fine needle aspiration (FNA) or core needle biopsy. In FNA, a very thin needle is used to withdraw fluid and cells from the suspicious tissue mass. This method has an advantage in that it is very low-pain, so low-pain that local anesthetic is not always used because the application of it may be more painful than the FNA itself. However, a shortcoming of FNA is that only a small number of cells are obtained through the procedure, rendering it relatively less useful in analyzing

2

the suspicious tissue and making an assessment of the progression of the cancer less simple if the sample is found to be malignant.

During a core needle biopsy, a small tissue sample is removed allowing for a pathological assessment of the tissue, including an assessment of the progression of any cancerous cells that are found. The following patent documents disclose various core biopsy devices and are incorporated herein by reference in their entirety: U.S. Pat. No. 6,273,862 issued Aug. 14, 2001; U.S. Pat. No. 6,231,522 issued May 15, 2001; U.S. Pat. No. 6,228,055 issued May 8, 2001; U.S. Pat. No. 6,120,462 issued Sep. 19, 2000; U.S. Pat. No. 6,086,544 issued Jul. 11, 2000; U.S. Pat. No. 6,077,230 issued Jun. 20, 2000; U.S. Pat. No. 6,017,316 issued Jan. 25, 2000; U.S. Pat. No. 6,007,497 issued Dec. 28, 1999; U.S. Pat. No. 5,980,469 issued Nov. 9, 1999; U.S. Pat. No. 5,964,716 issued Oct. 12, 1999; U.S. Pat. No. 5,928,164 issued Jul. 27, 1999; U.S. Pat. No. 5,775,333 issued Jul. 7, 1998; U.S. Pat. No. 5,769,086 issued Jun. 23, 1998; U.S. Pat. No. 5,649,547 issued Jul. 22, 1997; U.S. Pat. No. 5,526,822 issued Jun. 18, 1996; and US Patent Application 2003/0199753 published Oct. 23, 2003 to Hibner et al.

At present, a biopsy instrument marketed under the trade name MAMMOTOME is commercially available from ETHICON ENDO-SURGERY, INC. for use in obtaining breast biopsy samples. This device generally retrieves multiple core biopsy samples from one insertion into breast tissue with vacuum assistance. In particular, a cutter tube is extended into a probe to cut tissue prolapsed into a side aperture under vacuum assistance and then the cutter tube is fully retracted between cuts to extract the sample, deposited upon an externally exposed surface accessible by a grasping instrument.

With a long probe, the rate of sample taking is limited not only by the time required to rotate or reposition the probe but also by the time needed to translate the cutter. As an alternative to this "long stroke" biopsy device, a "short stroke" biopsy device is described in the following commonly assigned patent applications: U.S. patent application Ser. No. 10/676,944, "Biopsy Instrument with Internal Specimen Collection Mechanism" filed Sep. 30, 2003 in the name of Hibner et al. The cutter is cycled across the side aperture, reducing the sample time. Several alternative specimen collection mechanisms are described that draw samples through the cutter tube, all of which allow for taking multiple samples without removing the probe from the breast.

In particular, in the cross referenced U.S. patent application Ser. No. 10/953,834, "BIOPSY APPARATUS AND METHOD", these tissue samples are drawn by vacuum proximally through the cutter tube into a serial tissue stacking assembly that preserves the order of sample taking can be visually observed through a transparent lumen, and can serve as a transport container for samples taken during a pathology examination.

Some clinicians prefer to capture a plurality of biopsy samples in a small canister attached to a proximal end of the biopsy instrument, such as described in U.S. Pat. No. 6,638,235 to Miller and U.S. Pat. Appl. Publ. No. 2006/0260994 to Mark. Vacuum draws these samples into the canister while allowing fluids to pass through tubing back to a fluid capturing receptacle. Periodically, the canister is disengaged from the biopsy instrument for removing each sample and sending to pathology professionals for assessment.

While these known tissue storage approaches have a number of advantages, bodily tissues and fluids present a biological hazard to medical personnel that must be controlled while not interfering with the efficiency of the biopsy procedure.

SUMMARY OF THE INVENTION

The present invention addresses these and other problems of the prior art by providing a biopsy device that has a probe cannula that is inserted into tissue to obtain a core biopsy sample by translating a cutter with the probe cannula. A pneumatic pressure differential is used to draw a severed tissue sample proximally from the probe cannula into a biopsy sample and fluid capturing canister sized to complete a full biopsy and therapy procedure and to provide a convenient method of transporting the same to a pathology professional for sample assessment. Contact with the biopsy samples and extracted bodily fluids is avoided in that the container need not be opened in a biopsy suite. In addition, the overall volume of single patient use disposable items is reduced by combining the fluid collection and sample collection containers into a single reservoir, thereby reducing the volume of product inventory and biohazard waste materials.

These and other objects and advantages of the present invention shall be made apparent from the accompanying drawings and the description thereof.

BRIEF DESCRIPTION OF THE DRAWINGS

While the specification concludes with claims particularly pointing out and distinctly claiming the present invention, it is believed the same will be better understood by reference to the following description, taken in conjunction with the accompanying drawings in which:

FIG. 1 is an isometric view of a self-contained biopsy system including a biopsy device with cover omitted in fluid communication with the biopsy sample and fluid capturing canister.

FIG. 2 is an isometric view of the biopsy device of FIG. 1 with the cover and lower handle tray omitted and a reusable handpiece disengaged from a disposable probe assembly.

FIG. 3 is an exploded view from below, left of the disposable probe assembly of FIG. 2.

FIG. 4 is an isometric view from left, aft of the disposable probe assembly of FIG. 2 cut away to expose a pneumatic sequencing spool valve.

FIG. 5 is an exploded view of the biopsy sample and fluid capturing canister of FIG. 1.

FIG. 6 is a vertical cross section bisecting the biopsy sample and fluid capturing canister of FIG. 1.

FIG. 7 is a vertical cross section bisecting an alternative biopsy sample and fluid capturing canister for the biopsy system of FIG. 1.

DETAILED DESCRIPTION OF THE INVENTION

Turning to the Drawings, wherein like numerals denote like components throughout the several views, in FIG. 1, a biopsy device 10 includes a reusable handpiece 12 and a disposable probe assembly 14. A self-contained biopsy system 16 is formed by attaching a replaceable biopsy sample and fluid capturing canister 18. The canister 18 is generally sized to accommodate comfortably a volume of fluid that would be extracted, including saline flushing during a biopsy procedure with sufficient internal volume as well to hold biopsy tissue samples 19 (FIG. 6). As such, biohazards associated with bodily tissue and fluids are mitigated in that all such materials are readily transported from a biopsy suite for pathology assessment without the necessity of on-site access.

Tissue is drawn by vacuum assistance generated by vacuum pump 20 integral to the reusable handpiece 12 into a side aperture 22 of a probe cannula 24 of the disposable probe

assembly 14. The pneumatic vacuum assistance is achieved via a cutter tube 26 (exposed in the side aperture 22) that translates within a cutter lumen 28 of the probe cannula 24 and via an under slung lateral lumen 30 that distally communicates to the cutter lumen 28 through holes or apertures (not shown) just proximal to a piercing tip 32 of the probe cannula 24. A DC motor 34 in the reusable handpiece 12 powers rotation and translation of the cutter tube 26 to effect the severing.

The disposable probe assembly 14 responds to the position of the cutter tube 26 by sequencing pneumatic communication between the biopsy probe device 10 and the replaceable canister 18 via a vacuum supply line 36, a needle vacuum line 38, and a sample retraction line 40. The vacuum supply line 36 receives vacuum pressure at its distal end from the vacuum pump 20 and proximally passes through and proximally is engaged over a hose nib 42 formed onto the canister lid 44 of the canister 18. The needle vacuum line 38 distally communicates to a pneumatic sequencing spool valve 46 in the disposable probe assembly 14 and is frictionally held within a first protruding cylindrical hose receptacle 48 formed onto a canister lid 44 of the canister 18. The sample retraction line 40 distally communicates to the disposable probe assembly 14 and proximally passes through and is frictionally held within a second protruding cylindrical hose receptacle 50.

The reusable handpiece 12 includes a pneumatic manifold 52 having an upper right port 54 connected to the vacuum supply line 36 and an upper left port 56 open to atmosphere. It should be appreciated that the manifold 52 serves as a mounting for the vacuum pump 20 that generates the pressure differential between the ports 54, 56.

With particular reference to FIGS. 1-2, insertion of the probe cannula 24 into tissue is integrally supported by the piercing tip 32 attached at the distal end as well as a longitudinal jack hammer motion to the probe cannula 24 selected by positioning a slide button 58 distally and depressing a forward motor button 60. In response, the DC motor 34 drives a transmission section 61 grounded to a top cover 64 (depicted in phantom in FIG. 1) of the reusable handpiece 12 to longitudinally reciprocate an internal carriage frame assembly 62 that is engaged for movement with the probe cannula 24. With the slide button 58 proximally positioned, depression of the forward motor button 60 causes the DC motor 34 to advance and rotate the cutter tube 26, depicted in FIG. 1 as having been fully distally translated, closing the side aperture 20. Depression of a reverse motor button 68 causes the cutter tube 26 to retract. Depression of a mode button 70 may cause other functions to be performed. An additional feature contemplated but not depicted includes using the mode button 70 to selectively communicate a saline supply to the lateral lumen 30 to flush the probe cannula 24. It should be appreciated that the biopsy device 10 includes a minimum of "tethers" that would impede use, pose a tripping hazard, prevent use in an austere clinical setting, or extend set-up time.

Alternatively, instead of "hard-walled" lateral lumen 30 separated from the cutter lumen 28 along its length, applications consistent with the present invention may have a cylindrical probe cannula (not depicted) wherein the cutter tube 26 is positioned off-center to translate across a side aperture. A "soft-walled" lateral lumen may then be defined as a space between an outer diameter of the cutter tube and an inner diameter of the cylindrical probe cannula.

In FIGS. 1-4, the disposable probe assembly 14 has a bottom cover 78 with a distal probe mount cover 80 that assists in supporting the probe cannula 24 while allowing the longitudinal jack hammer motion. A plurality of locking tabs 82 with locking edges 84 extend upwardly through pass-

5

through slots (not shown) formed in the periphery of a lower handle tray **86** (FIG. 1) attached to the cover **64** of the reusable handpiece **12** to resiliently extend outwardly into engaging contact with the slots facilitating replacement of the disposable probe assembly **14**. Relieved areas **88** are formed behind each locking tab **82** in a top extension member **89** that surrounds a probe support body **90**. The combination covers a cavity defined by the bottom cover **78**, which allows depression of the locking tabs **82** to unlock the disposable probe assembly **14** to install another identical or similar assembly.

A proximal end of the cutter tube **26** receives a cutter gear **92** having distal and proximal reduced diameter bearing surfaces **94**, **96** on each longitudinal side of a rotation spur gear section **98**, which engage the reusable handpiece **12** for rotation and for longitudinal translation through a distally open longitudinal aperture **100** (FIG. 3) formed in the bottom cover **78**.

In FIGS. 2-4, the disposable probe assembly **14** has movable components that respond to the actuating motions of the reusable handpiece **12**. The probe support body **90** includes a distal probe mount **106** that is received within the distal probe mount cover **80** of the bottom cover **78**. Proximal to and underlying a longitudinal axis of the disposable probe assembly **14** defined by a probe guide hole **108** passing through the distal probe mount **106**, a vertically open longitudinal slot **110** is formed into a necked portion **112** of the probe support body **90**.

With particular reference to FIGS. 3-4, at a proximal end of the longitudinal trough **110**, a distally open, longitudinally aligned valve bore **114** is formed in a proximal block portion **116** of the probe support body **90**. Central and proximal ports **118**, **120** communicate with the valve bore **114** laterally from a left side of the proximal block portion **116** and a distal port **122** communicates laterally from a right side of the proximal block portion **116**. A right distal ninety-degree fitting **124** communicates between the distal port **122** and an intake filter **128**.

A valve control rod **130** has a prismatic distal actuating portion **132** extending distally out of the valve bore **114** constrained for only longitudinally movement within the longitudinal slot **110**. The valve control rod **130** also has a valve spool portion **134** that longitudinally translates within the valve bore **114** to selectively position between a first position and a second position. A proximal O-ring **136** near a proximal end of the valve spool portion **134** and a distal O-ring **138** are spaced such that the first position entails the O-rings **136**, **138** bracketing the central and distal ports **118**, **122** (i.e., distal position of the valve control rod **130**) and the second position entails the O-rings **136**, **138** bracketing the proximal and central ports **120**, **118**, respectively (i.e., proximal position of the valve control rod **130**).

A distal vacuum conduit **140** has one end attached to a center ninety-degree fitting **142** attached to the central port **118** and the other end attached to a probe union ninety-degree fitting **144** that communicates with the lateral lumen **30**. The needle vacuum line **38** has its distal end attached to a proximal ninety degree fitting **146** attached to the proximal port **120**.

A front actuation finger **148** (FIG. 2) of a front carriage **150** is received within an upwardly open socket **152** formed on a left side of a vacuum control shuttle **154** having a lateral concave recessed band **156** shaped to encompass with a clearance a lower portion of the rotation spur gear section **98** of the cutter gear **92**. The vacuum control shuttle **154** is laterally sized to bridge the longitudinal slot **110** with a downwardly projecting vacuum actuator lug **157** (FIG. 3) attached to an underside of the shuttle **154** that is received within a vertically open elongate delay slot **158** of the distal actuating end **132** of

6

the vacuum control rod **130**. Thus, the rather long cutter travel is translated into a smaller valve movement as the shuttle reaches either full proximal or full distal travel.

A sample retraction line **40** is proximally held by a tube guide **162** extending inwardly from proximal end of the top extension member **89** of the disposable probe assembly **14**. A distal end of the longitudinally aligned sample retraction line **40** is received through a rear dynamic seal **164** attached to a proximal end of the cutter gear **92**, and into the cutter tube **26**.

The reusable handpiece **12** of the biopsy device **10** is substantially as described in greater detail in four commonly-owned and co-pending U.S. patent applications (1) Ser. No. 11/198,558, "Biopsy Device With Replaceable Probe And Incorporating Vibration Insertion Assist And Static Vacuum Source Sample Stacking Retrieval" to Hibner et al., filed 8 Aug. 2005, published as US 2007-0032741 A1; (2) Ser. No. 11/736,117, "Tissue Sample Revolver Drum Biopsy Device" to Hibner et al., filed 17 Apr. 2007; (3) Ser. No. 11/753,665, "Tissue Sample Serial Capturing Biopsy Device" to Hibner, filed 25 May 2007; and (4) Ser. No. 11/465,143 "Vacuum Syringe Assisted Biopsy Device" to Hibner, filed 17 Aug. 2006, published as US 2007-0032743 A1, the disclosures of all of which are hereby incorporated by reference in their entirety. An aft carriage is omitted from the illustrative version for clarity as not being necessary, although a common reusable handpiece may include a second carriage for mounting to other types of disposable probe assemblies as described in the cross referenced applications.

In FIGS. 5-6, the biopsy sample and fluid capturing canister **18** has a tapered cylindrical fluid container **170** whose upper band-shaped lip seals **172** to and is encompassed by a downward circumferential lip **174** of the canister lid **44**. A sample collector basket **176** has tapered cylindrical sides **178** shaped to come to rest at approximately a midpoint of the interior of the fluid container **170**. Near the top of the tapered cylindrical sides **178** of the sample collector basket **176**, a perforated disk **180** is horizontally attached to serve as support to a filter disk **182** adhered to an undersurface. The combination acts in a similar fashion to a drip coffee filter basket. About approximately a third of the upper circumference of the cylindrical sides **178** of the sample collector basket **176**, a raised side wall portion **184** culminates in a horizontal and inwardly projecting annular ring portion **186** that serves as a handle for drawing the sample collector basket **176** out of the fluid container **170**.

The center of the perforated disk **180** of the sample collector basket **176** includes a first hose receptacle **188** registered for the needle vacuum line **38** to pass on downward into a fluid collection reservoir **190** formed within the fluid container **170** below the perforated disk **180** of the sample collector basket **176**. The center of the perforated disk **180** of the sample collector basket **176** also includes a second hose receptacle **192** registered for the sample retraction line **40** to pass on downward into the fluid collection reservoir **190**. It should be appreciated that caps or a closed lid (not shown) may be used to seal the biopsy sample and fluid capturing canister **18** after the lines **36**, **38**, **40** are removed.

With reference to FIGS. 4 and 6, in use, the cutter **26** is initially distally positioned as the probe cannula **24** is inserted into tissue. The vacuum motor **20** operates providing a low pressure within the fluid collection reservoir **190** inside of the replaceable canister **18** via vacuum supply line **36**. A hydrophobic filter **198** prevents fluids from reaching the vacuum motor **20**. The low pressure communicates to the cutter tube **26** via the sample retraction line **40**. After the probe cannula **24** is inserted into tissue beside a suspicious lesion, the cutter tube **26** is retracted. The spool valve **46** is in the first position,

7

with the vacuum lumen 30 vented to atmosphere via central port 118 and distal port 122. The retraction of the cutter gear 92 causes the shuttle 154 to retract correspondingly with its downward lug 152 moving within the delay slot 158 of the distal actuating portion 132 of the valve control rod 130. Once the carriage 150 of the reusable handpiece 12 reaches full proximal travel, the lug 157 contacts the proximal end of the delay slot 158 and changes the pneumatic sequencing spool valve 46 from the first position to the second position. Thus, the vacuum lumen 30 is also exposed to vacuum via central and proximal ports 118, 120 of the spool valve 46 that communicates via the needle vacuum line 38 to the replaceable container 18, exposing the suspicious lesion to the vacuum assistance from both lines 38, 40 to prolapse tissue into the side aperture 20. The spool valve 46 stays in this configuration as the cutter tube 26 is advanced distally while rotating to sever the tissue sample 19. As the shuttle 154 approaches its distal-most position, the lug 157 contacts the distal end of the delay slot 158 of the distal actuating portion 132 of the valve control rod 130, changing to the first position wherein the vacuum lumen 30 is vented to atmosphere and the tissue sample 19 is retracted into the replaceable container 18 by vacuum pressure via the sample retraction line 40.

Once tissue samples 19 are collected in the replaceable container 18, the replaceable container 18 is removed from the biopsy device 10 and transported to a pathology professional for sample assessment.

Alternately, the bodily fluids are drained from the container and replaced with tissue preparation fluid (e.g. Formalin) prior to being sent off for pathological assessment. The bodily fluids are removed from the replaceable canister 18 by removing the canister lid 44, needle vacuum line 38, and the sample retraction line 40 from the replaceable canister assembly 18. While supporting the tapered cylindrical fluid container 170 and the annular ring portion 186 located on sample collector basket 176, the fluids are poured from the tapered cylindrical fluid container 170 with the tissue samples 19 remaining in the tapered cylindrical fluid container 170. The sample collector basket 176 and attached filter disk 182 are then removed from the tapered cylindrical fluid container 170 and tissue preparation fluid (e.g. Formalin) is poured into the tapered cylindrical fluid container 170. A canister lid (not shown) without hose receptacles or nibs is attached to the tapered cylindrical fluid container 170 prior to transporting to a pathology professional for sample assessment. Alternately, after the fluids are poured from the tapered cylindrical fluid container 170, the sample collector basket 176, and attached filter disk 182 are removed from the tapered cylindrical fluid container 170. The tissue samples 19 are transferred from the tapered cylindrical fluid container 170 into a container (not shown) containing tissue preparation fluid (e.g. formalin) prior to transportation to a pathology professional for sample assessment.

Another alternate embodiment of a biopsy sample and fluid capturing canister 18 is depicted in FIG. 7 as including a fully enclosed sample collector basket 192 with a lower perforated disk 194 and filter 196 to fully contain the tissue samples 19 as they exit sample retraction line 40. The lower perforated disk 194 and filter 196 act to separate the tissue samples 19 from bodily fluids. Once tissue samples 19 are collected in the replaceable container 18, the fully enclosed sample collector basket 192 can be removed from the replaceable container 18 and placed directly into a container (not shown) containing tissue preparation fluid (e.g. Formalin) prior to transportation to a pathology professional for sample assessment.

It should be appreciated that any patent, publication, or other disclosure material, in whole or in part, that is said to be

8

incorporated by reference herein is incorporated herein only to the extent that the incorporated material does not conflict with existing definitions, statements, or other disclosure material set forth in this disclosure. As such, and to the extent necessary, the disclosure as explicitly set forth herein supersedes any conflicting material incorporated herein by reference. Any material, or portion thereof, that is said to be incorporated by reference herein, but which conflicts with existing definitions, statements, or other disclosure material set forth herein, will only be incorporated to the extent that no conflict arises between that incorporated material and the existing disclosure material.

While preferred embodiments of the present invention have been shown and described herein, it will be obvious to those skilled in the art, given the benefit of the present disclosure, that such embodiments are provided by way of example only. Numerous variations, changes, and substitutions will now occur to those skilled in the art without departing from the spirit and scope of the appended claims.

For example, as a means to further reduce the size and weight of the overall biopsy device 10, the DC motor 34 employed to rotate and translate the cutter tube 26 can also drive the vacuum pump 20 via appropriate gearing.

For another example, although the integral vacuum pump advantageously makes the biopsy device 10 more self-sufficient in austere clinical situations, applications consistent with aspects of the invention may employ a separate vacuum source.

As another example, while a DC motor integral to the reusable handpiece has certain advantages in the illustrative version, applications consistent with aspects of the invention may utilize a motor comprising materials compatible with use in a strong magnetic environment (e.g., magnetic resonance imaging) or remotely placed (e.g., via a drive cable).

As another example, while a pneumatically closed system between the replaceable container 18 and the biopsy device 10 provides various advantages, applications consistent with aspects of the invention may provide separate vacuum source connections to the biopsy device and to the replaceable container 18.

What is claimed is:

1. A biopsy device comprising:

- a. a body;
- b. a probe cannula defining an internal passage and having a side aperture, wherein the probe cannula is configured to extend distally from the body;
- c. a cutter translatable relative to the probe cannula to sever a tissue sample received in the probe cannula;
- d. a vacuum source in communication with the cutter;
- e. a tissue sample holder comprising:
 - i. a vacuum port positioned on an exterior surface of the tissue sample holder, wherein the vacuum port is configured to communicate with the vacuum source, and
 - ii. a removable portion selectively removable from the tissue sample holder, wherein the removable portion comprises a straining member configured to separate fluids from solids, wherein the removable portion is configured to hold solid tissue samples; and
- f. a flexible tube coupling the tissue sample holder with the body such that the tissue sample holder is flexibly spaced away from the body.

2. The biopsy device of claim 1, further comprising a first conduit between the tissue sample holder and a proximal end of the cutter, wherein the first conduit is configured to communicate solid tissue samples to the tissue sample holder.

3. The biopsy device of claim 2, wherein the first conduit is flexible.

9

4. The biopsy device of claim 2, wherein the first conduit passes through a plane defined by the straining member and terminates at a free end within the tissue sample holder.

5. The biopsy device of claim 2, wherein the first conduit is positioned above a plane defined by the straining member and terminates at free end within the tissue sample holder.

6. The biopsy device of claim 2, further comprising a vacuum lumen communicating to a distal end of the probe cannula and a second conduit between the container and the vacuum lumen, wherein the second conduit is configured to communicate vacuum with the vacuum lumen.

7. The biopsy device of claim 6, wherein the second conduit passes through a plane defined by the straining member and terminates at a free end within the tissue sample holder.

8. The biopsy device of claim 6, wherein the second conduit is positioned above a plane defined by the straining member and terminates at a free end within the tissue sample holder.

9. The biopsy device of claim 6, further comprising a vacuum lumen communicating to a distal end of the probe cannula and a pneumatic switching assembly responsive to the cutter, wherein the pneumatic switching assembly is operatively configured to expose both the cutter and the vacuum lumen from the vacuum source in response to the cutter being retracted to prolapse tissue into the side aperture, wherein the pneumatic switching assembly is responsive to the cutter being distally positioned to expose the vacuum lumen to an increased pressure to effect retraction of severed tissue to the container via the first conduit.

10. The biopsy device of claim 1, wherein the tissue sample holder is defined by a fluid reservoir and the straining member.

11. The biopsy device of claim 1, wherein the tissue sample holder is configured to hold solid tissue samples separately from a fluid reservoir.

12. The biopsy device of claim 11, wherein the removable portion of the tissue sample holder comprises a basket.

13. The biopsy device of claim 12, wherein the basket is configured to hold solid tissue samples while permitting fluid to flow through the basket.

14. The biopsy device of claim 1, wherein the vacuum port is positioned above the straining member.

15. The biopsy device of claim 1, further comprising a motor assembly operatively configured to translate the cutter to sever a tissue sample.

10

16. A biopsy device comprising:

- a. a probe cannula defining an internal passage and having a side aperture;
- b. a cutter translatable relative to the probe cannula to sever a tissue sample received in the probe cannula;
- c. a vacuum source in communication with the cutter;
- d. a container at a reduced pneumatic pressure, wherein the container comprises:
 - i. a straining member configured to separate fluids from solids, and
 - ii. a tissue sample holder located in the container, wherein the tissue sample holder is configured to hold solid tissue samples within the container; and
- e. a first conduit between the container and a proximal end of the cutter, wherein the first conduit is configured to communicate solid tissue samples to the tissue sample holder, wherein the first conduit is configured to extend through the straining member.

17. A biopsy device comprising:

- a. a probe portion comprising:
 - i. a cannula defining an internal passage and having a side aperture, and
 - ii. a cutter translatable relative to the probe cannula to sever a tissue sample received in the probe cannula;
- b. a vacuum source in communication with the cutter;
- c. a tissue sample holder comprising a straining member configured to separate fluids from solids, wherein the tissue sample holder is configured to hold solid tissue samples severed by the cutter;
- d. a first conduit between the tissue sample holder and the probe portion, wherein the first conduit is configured to communicate solid tissue samples to the tissue sample holder; and
- e. a second conduit between the tissue sample holder and the probe portion, wherein the second conduit is configured to communicate vacuum with the cutter.

18. The biopsy device of claim 17, wherein the tissue sample holder further comprises a lid, wherein the first and second conduits are configured to engage the lid.

19. The biopsy device of claim 17, wherein the first and second conduits terminate at a free end located above the straining member.

20. The biopsy device of claim 17, wherein the straining member comprises a perforated disk and a filter disk.

UNITED STATES PATENT AND TRADEMARK OFFICE
CERTIFICATE OF CORRECTION

PATENT NO. : 9,265,485 B2
APPLICATION NO. : 14/188744
DATED : February 23, 2016
INVENTOR(S) : John A. Hibner

Page 1 of 1

It is certified that error appears in the above-identified patent and that said Letters Patent is hereby corrected as shown below:

In the claims,

Column 9, Claim 6, line 9, reads "...the container..." which should be deleted and replaced with "...a container...".

Column 9, Claim 9, lines 19-20 read "...a vacuum lumen communicating to a distal end of the probe cannula and..." which should be deleted.

Column 9, Claim 9, line 25 reads "...the side aperture..." which should be deleted and replaced with "...a side aperture...".

Column 10, Claim 17, line 24 reads "...the probe cannula..." which should be deleted and replaced with "...a probe cannula".
